Musculoskeletal Exams
Systematic Musculoskeletal Examinations is a clear, step-by-step learning text, atlas, and video series designed to teach essential and foundational skills of musculoskeletal physical assessment. Systematic Musculoskeletal Examinations presents a 3-part learning system:

1. Screening Musculoskeletal Examination (SMSE): rapid assessment of structure and function.
2. General Musculoskeletal Examination (GMSE): comprehensive assessment of joint inflammation and arthritis.
3. Regional Musculoskeletal Examination (RMSE): focused assessments of structure and function combined with special testing of the shoulder, knee, and neck and low back.

[Next question >](#)

You correctly answered E.

All the following are vitamin K-dependent coagulation factors except

- ☐ A. factor X
- ☐ B. factor VII
- ☐ C. protein C
- ☐ D. protein S
- ☐ E. factor VIII

The answer is E.

The answer is .

Vitamin K is a fat-soluble vitamin that plays an essential role in hemostasis. It is absorbed in the small intestine and stored in the liver. It serves as a cofactor in the enzymatic carboxylation of glutamic acid residues on prothrombin-complex proteins. The three major causes of vitamin K deficiency are poor dietary intake, intestinal malabsorption, and liver disease. The prothrombin complex proteins (factors II, VII, IX, and X and protein C and protein S) all decrease with vitamin K deficiency. Factor VII and protein C have the shortest half-lives of these factors and therefore decrease first. Therefore, vitamin K deficiency manifests with prolongation of the prothrombin time first. With severe deficiency, the aPTT will be prolonged as well. Factor VIII is not influenced by vitamin K.

Diagnostic Tests > Common Laboratory Tests >

This section contains information about commonly used laboratory tests. It includes most of the blood, urine, and cerebrospinal fluid tests found in this book, with the exception of drug levels. Entries are in outline format and are arranged alphabetically.

Test/Reference Range/Collection

This first outline listing begins with the common test name, the specimen analyzed, and any test name abbreviation (in parentheses).

Below this in the first outline listing is the reference range for each test. The first entry is in conventional units, and the second entry (in [brackets]) is in SI units (Système International d'Unités). Any panic values for a particular test are placed here after the word **Panic**. The reference ranges provided are from several large medical centers; consult your own clinical laboratory for those used in your institution.

This outline listing also shows which tube to use for collecting blood and other body fluids, how much the test costs (in relative symbolism; see below), and how to collect the specimen. Listed below are the common collection tubes and their contents:

Tube Top Color	Tube Contents	Typically Used In
Lavender	EDTA	Complete blood count; molecular testing

Alkaline Phosphatase			
Test/Range/Collection	Physiologic Basis	Interpretation	Comments
Alkaline phosphatase, serum 41–133 IU/L [0.7–2.2 mkat/L] (method- and age-dependent) SST \$ Key	Alkaline phosphatases are found in liver, bone, intestine, and placenta.	Increased in: Obstructive hepatobiliary disease, bone disease (physiologic bone growth, Paget disease, osteomalacia, osteogenic sarcoma, bone metastases), hyperparathyroidism, rickets, benign familial hyperphosphatasemia, pregnancy (third trimester), GI disease (perforated ulcer or bowel infarct), hepatotoxic drugs. Decreased in: Hypophosphatasia.	Alkaline phosphatase performs well in measuring the extent of bone metastases in prostate cancer. Normal in osteoporosis. Alkaline phosphatase isoenzyme separation by electrophoresis or differential heat inactivation is unreliable. Use γ -glutamyl transpeptidase, which increases in hepatobiliary disease but not in bone disease, to infer origin of increased alkaline phosphatase (ie, liver rather than bone). Disease Screening	Organization	Date	Population	Recommendations	Comments	Source
Anemia	AAFP	2006	Infants aged 6–12 months	Perform selective, single hemoglobin or hematocrit screening for high-risk infants.*	Reticulocyte hemoglobin content is a more sensitive and specific marker than is serum hemoglobin level for iron deficiency. One-third of patients with iron deficiency will have a hemoglobin level > 11 g/dL.	http://www.aafp.org/online/en/home/clinical/exam.html
	USPSTF	2006	Infants aged 6–12 months	Evidence is insufficient to recommend for or against routine screening, but risk assessment based on diet, socioeconomic status, prematurity, and low birth weight should be done.	Recommends routine iron supplementation in high-risk children aged 6–12 months.	
	USPSTF	2006	Pregnant women	Screen all women with hemoglobin or hematocrit at first prenatal visit.	<ol style="list-style-type: none">1. Insufficient evidence to recommend for or against routine use of iron supplements for nonanemic pregnant women (USPSTF).2. When acute stress or inflammatory disorders are not present, a serum ferritin level is the most accurate test for evaluating iron deficiency anemia. Among women of childbearing age, a cut-off of 30 ng/mL has sensitivity of 92%, specificity of 98% (Blood. 1997;89:1052–1057).3. Severe anemia (hemoglobin < 6) associated with abnormal fetal oxygenation and transfusion should be considered. In iron-deficient women intolerant of oral iron, intravenous iron sucrose or iron dextran should be given.	http://www.ahrq.gov/clinic/cpgsix.htm

Asthma

From POSTGRADUATE MEDICINE / VOL 113 / NO 3

You often have trouble breathing, especially when you exercise or vacuum your carpet. But it also happens when you're not exercising. Sometimes you even wake up wheezing during the night. Your doctor tells you that you have asthma, a long-term disease that affects more than 17 million men, women, and children in the United States.

What is asthma?
Asthma is a disease in which a person's airways become inflamed, swollen, and narrowed, making it difficult for air to flow into and out of the lungs. When the airways are swollen, breathlessness and other symptoms of asthma occur.

Inappropriate therapies (i.e., therapies delivered in the absence of a ventricular tachyarrhythmia, such as when a supraventricular tachyarrhythmia is erroneously categorized by the device as a ventricular arrhythmia) account for a sizeable portion of total therapies delivered by implantable cardioverter defibrillators (ICDs). While it is theoretically possible to alter ICD programming to decrease the risk of inappropriate therapies, such programming changes could increase the risk of syncope and/or mortality due to delay or failure to deliver appropriate therapies.

The MADIT-RIT trial (Moss et al., 2012) was a randomized, controlled trial examining the effects of (1) a higher rate cutoff to trigger delivery of therapy for tachyarrhythmias (ventricular tachycardia (VT) monitor zone without therapy at 170 bpm, ventricular fibrillation (VF) zone at
